ABSTRACT

This study evaluated the sealing ability of apical plugs fabricated with gray MTA Angelus™ sealer, CPM™ sealer and MBPc sealer. The root canals of 98 extracted single-rooted human teeth were instrumented with #5 to #1 Gates Glidden drills according to the crown-down technique until the #1 drill could pass through the apical foramen. The specimens were then prepared with K-files, starting with an ISO 50 until an ISO 90 could be visualized 1 mm beyond the apex. After root canal preparation, the external surface of each root was rendered impermeable and roots were assigned to 3 experimental groups (n = 30), which received a 5-mm thick apical plug of gray MTA Angelus™, CPM™ and MBPc, and two control groups (n=4). The remaining portion of the canal in the experimental groups was filled by the lateral condensation technique. The teeth of each group, properly identified, were fixed on utility wax by their crowns and were placed in plastic flasks, leaving the apex free and facing upward. The flasks were filled with 0.2% Rhodamine B solution, pH 7.0, so as to completely cover the root apex of all teeth. The sealing ability was analyzed by measuring 0.2% Rhodamine B leakage after all groups had been maintained in this solution for 48 hours. Data were analyzed statistically by Kruskal-Wallis test and Dunn test with a=5%. The results showed that, among the tested materials used for fabrication of apical plugs, MBPc sealer had the least amount of leakage with statistically significant difference (p<0.05).

INTRODUCTION

When teeth with incomplete root formation undergo pulp necrosis, dentin formation is interrupted and root development ceases. Consequently, the root canal is large, with thin and fragile walls, and the apex remains open. These features impair root canal instrumentation and prevent the achievement of an adequate apical stop. In such cases, in order to allow condensation of the filling material and promote apical sealing, it is imperative to create an artificial apical barrier or induce closure of the apical foramen with calcified tissue (apexification). Calcium hydroxide apexification has been successfully used for years, yet requires patient compliance and multiple sessions. In an attempt to eliminate these problems, especially the need of multiple sessions, some materials have been used as apical plugs.

In addition to calcium hydroxide, used in powder or paste forms, other materials have been used as apical plugs, especially dentin chips. Recently, many studies and some case reports have shown the use of MTA for fabrication of apical plugs. MTA was developed by Torabinejad in the early 1990’s; the first study on this material was published by Lee, et al. in 1993. The main components of MTA are tricalcium oxide, tricalcium silicate, bismuth oxide, tricalcium aluminate, tricalcium oxide, tetracalcium aluminoferrite and silicate oxide. In addition, there are a few other mineral oxides, which are responsible for the chemical and physical properties of MTA. The powder consists of fine hydrophilic particles that form a colloidal gel in the presence of water or moisture; this gel solidifies to form a hard sealer in less than four hours. In 2001, the company Angelus Soluções Odontológicas introduced the MTA developed in Brazil, which is apparently identical to the MTA developed by Torabinejad.

In 2004, CPM™ was developed in Argentina (Egeo S.R.L., Buenos Aires, Argentina), which is also a MTA for clinical use, similar to MTA. The powder also consists of fine hydrophilic particles that form a colloidal gel in presence of...
The main components are tricalcium silicate, tricalcium oxide, tricalcium aluminate and other oxides5.

In 1984, the investigators Ivaldo Gomes de Moraes, DDS, PhD, and Alceu Berbert, DDS, PhD, from the Department of Operative Dentistry, Dental Materials and Endodontics of the Dental School of Bauru, University of São Paulo, Brazil, developed a new epoxy resin sealer containing calcium hydroxide (MBPc), introduced as a retrograde filling material. MBPc is packed in glass vials as a hydrophobic paste/paste sealer, mixed in a 4:1 ratio (base paste/catalyst paste) with 4 hours of setting time6.

The purpose of this study was to evaluate the sealing ability of apical plugs fabricated with gray MTA Angelus™ sealer, CPM™ sealer and MBPc sealer, evaluated by leakage of 0.2% Rhodamine B dye.

**MATERIAL AND METHODS**

The study was approved by the Institutional Review Board of the Dental School of Bauru (133/2005). Ninety-eight extracted single-rooted human teeth were used for this study. The teeth were stored in 10% formalin and kept moist before the experiment. After coronal access, the canals were instrumented with #5 to #1 Gates Glidden drills (Dentsply-Maillefer Instruments SA, Ballaigues, Switzerland) by the crown-down technique until the #1 size drill could pass through the apical foramen. The specimens were then prepared with K-files (Dentsply-Maillefer Instruments SA, Ballaigues, Switzerland), starting with an ISO 50 until an ISO 90 could be visualized 1 mm beyond the root apex. The root canals were filled by the lateral condensation technique with gutta-percha and one drop of sterile water, and carried with a Lentulo spiral (Dentsply-Maillefer Instruments SA) at low speed up to 3 mm short of the apical foramen. The MTA was condensed up to the apical end with aid of an ISO 90 K-file wrapped in cotton. Another K-file involved with moistened cotton was used to remove the excess MTA from the dentinal walls. In case of overfilling, the excess material was also removed.

CPM™ (Egeo S.R.L., Buenos Aires, Argentina) was also prepared according to the manufacturer’s instructions, mixed at three portions of powder and one drop of saline solution, and carried with a Lentulo spiral in low speed as described for gray MTA Angelus™. CPM™ condensation and excess removal was performed as described for the MTA.

MBPc was mixed at a 4:1 ratio (base paste/catalyst paste). Before mixture, small cylindrical portions of the sealer were prepared, with smaller diameter than the root canal diameter. These cylinders were individually placed in the root canal using an ISO 70 K-file to the root canal end. The MBPc was condensed with pluggers and any overfilling material was removed with care avoid compressing the sealer against the apex. Radiographs were obtained from all teeth to check the thickness of the apical plug.

After fabrication of apical plugs, the remaining root canal portions were filled with a calcium hydroxide water-based paste (Odontopharma Indústria e Comércio Ltda, Porto Alegre, RS, Brazil) and placed in an oven at 37°C for 15 days. After this period, the calcium hydroxide water-based paste was removed by saline irrigation aided with files. The root canals were dried with paper points (Tanariman Industrial Ltda) and Sealer 26 (Dentsply-Maillefer Instruments SA), pH 7.0, so as to completely cover the root apex of all teeth. The flasks were filled with 0.2% Rhodamine B solution (Labsynth Produtos para Laboratórios Ltda, Araçatuba, SP, Brazil), pH 7.0, so as to completely cover the root apex of all teeth. The flasks were kept at 37°C for 48 hours. After this period, the teeth were removed from the dye and washed in tap water for 24 hours. The impermeable layer was removed with a LeCron spatula, and the teeth were brushed and further washed for 12 hours. After drying, the teeth were submitted to longitudinal sectioning on the proximal surface using carborundum discs, in order to expose the apical plug and part of the root canal filling.

Then, sets of five specimens were placed on a sheet of utility wax and photographed with a digital camera (Canon EOS Rebel 300 D) on a tripod. The teeth were also photographed close to a millimeter plastic ruler.

For analysis of the sealing ability of the tested materials, leakage of 0.2% Rhodamine B was linearly measured on the photographs using the Image Tool software version 3.0 (The University of Texas Health Science Center in San Antonio, UTHSCSA, San Antonio, TX, USA). Leakage measurement...
considered the line with longer length of dye, on the apical
plug-dentinal wall interface, from the most apical to the most
cervical portion. Leakage was independently measured by
eighteen calibrated examiners.

RESULTS

Kappa statistics showed that agreement between the three
examiners was higher than 90%. The results (mean of leakage
values obtained by each examiner) obtained in millimeters
were tabulated and analyzed by the Kruskal-Wallis test to
investigate possible differences between materials, and
Dunn’s test to confirm the significance of difference between
groups. Significance level was set at 5%.

Figure 1 represents the mean leakage of 0.2% Rhodamine
B, in millimeters, for the groups receiving the apical plug.

DISCUSSION

Several techniques have been used to analyze the sealing
ability of root canal filling and retrograde filling, including
evaluation of leakage of bacteria\textsuperscript{12,13,21}, human saliva\textsuperscript{1}, protein
complex\textsuperscript{14,15}, fluid filtration\textsuperscript{15} and dye leakage\textsuperscript{16,18,20,22,27}.

Among the dyes, use of methylene blue at different
concentrations has been outstanding\textsuperscript{16,18,22}. However, in 1998,
Wu, et al.\textsuperscript{26} conducted an interesting work and stated that
methylene blue suffers discoloration when in contact with
some alkaline filling materials, which may cause unrealistic
results of such materials in leakage studies. Methylene blue
discoloration occurs because it is unstable when in contact
with alkaline materials. Such materials cause hydrolysis of
methylene blue, resulting in formation of a clear compound
named thionine. This would explain why methylene blue is
discolored by calcium hydroxide. In relation to MTA, in the
presence of water, the calcium oxide in the material could form
calcium hydroxide, which would certainly cause discoloration
of methylene blue\textsuperscript{26}.

share the same opinion. Therefore, when performing the
leakage test to assess the sealing ability of gray MTA-
Angelus\textsuperscript{TM}, CPM\textsuperscript{TM} and MBPc, in this study, 0.2% Rhodamine
B was selected instead of methylene blue, based on the
previously mentioned studies, since labeling by Rhodamine
B is not influenced by alkaline materials\textsuperscript{19,21}.

Investigation of gray MTA has been based on the
frequency of utilization when apical plugs are necessary, with
excellent results\textsuperscript{4,10,17}. Gray MTA-Angelus\textsuperscript{TM} was used instead
of gray ProRoot MTA\textsuperscript{TM} (Dentsply/Tulsa Dental, United
States of America) in order to use a national product, which is
also easier to find in the market.

Concerning CPM\textsuperscript{TM}, according to the manufacturer, this
material has similar or better physical, chemical and biological
characteristics compared to MTA, with the same clinical
indications\textsuperscript{5}. As this material is also a mineral trioxide
aggregate, this study evaluated the possibility of using it as
apical plug, as well as its sealing ability and marginal
adaptation, since few studies are available on CPM\textsuperscript{TM}.

MBPc was also used because its physical and chemical
characteristics have been previously assessed, showing great
results\textsuperscript{20}; one study also assessed its biological properties\textsuperscript{6}.
As the initial clinical indications of this material included only
use for retrograde filling and in cases of root perforation\textsuperscript{18}, it
was deemed interesting to investigate the possibility of using this material for fabrication of apical plug.

The thickness of apical plug in different studies ranges from 1 mm\textsuperscript{11,24} to 10 mm\textsuperscript{3}. Nevertheless, the best results have more frequently been reported with apical plugs between 3 mm and 5 mm of thickness. Considering the studies of Matt, et al.\textsuperscript{18} (2004) and Al-Kahtani, et al.\textsuperscript{2} (2005), in which 5-mm-thick apical plugs showed the best results, this dimension was established for fabrication of the plugs in this study.

Data on Figure 1 show that, in general, the sealing ability of apical plugs with several types of material may be classified, in a descending numerical order, as follows: MBPc (1.99 ± 1.44 mm), Gray MTA-Angelus\textsuperscript{TM} (3.39 ± 1.39 mm) and CPM\textsuperscript{TM} (4.00 ± 1.00 mm). Dunn’s test showed that MBPc was significantly better than the other materials used as apical plugs (p<0.05).

The study of Bramante, et al.\textsuperscript{4} (2006) allows comparison between the results obtained with CPM\textsuperscript{TM} and those of the present results. According to those authors, CPM\textsuperscript{TM} has dimensional adhesion stability through time, among other properties. However, the results observed for this material with regard to sealing ability were not so good, with a mean overall leakage of 4.00 ± 1.00 mm.

Regarding MTA, the excellent sealing ability of both Pro Root\textsuperscript{TM} MTA and gray MTA-Angelus\textsuperscript{TM}, used in this study, have been highlighted by several authors\textsuperscript{16,18,22,27}. Conversely, in a recent study by Silva Neto and Moraes\textsuperscript{20} (2003), MTA was not considered as a good sealer. When used as an apical plug, especially with 4- to 5-mm thickness, MTA has shown great sealing ability\textsuperscript{2,11,24}. Consequently, the results observed for gray MTA-Angelus\textsuperscript{TM} in this study confirm those found in the aforementioned studies.

Regarding MBPc, the study testing its sealing ability (Silva Neto and Moraes\textsuperscript{20}, 2003, using Rhodamine B in perforations) has shown its ability as a good sealer. That fact was observed in this study, which revealed best outcomes for MBPc, with only 1.99 ± 1.44 mm of leakage, with statistically significant difference in relation to CPM\textsuperscript{TM} and gray MTA-Angelus\textsuperscript{TM}.

**CONCLUSION**

The results showed that, when analyzing the sealing ability of apical plugs of gray MTA-Angelus\textsuperscript{TM}, CPM\textsuperscript{TM} and MBPc, it was observed that MBPc presented the best results, with statistically significant difference compared to the other two materials.
